Cube Creation

Step1: We must first create a connection to the data source in visual studio. i.e. we will connect to the relational database called UK Accidents Database.

The Team12_MDM is our new analysis database.

UK Accidents Relational Database will act as the source of data for our Team12_MDM analysis database.

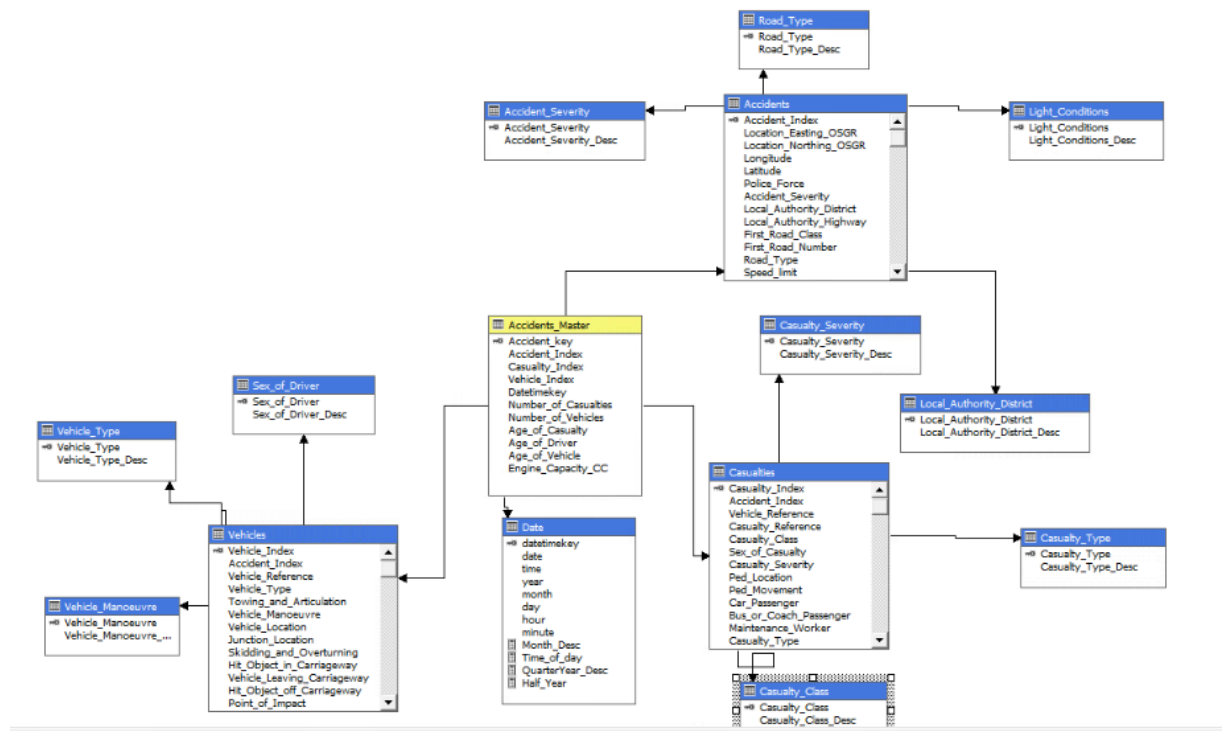

We see the new data source being connected to the UK Accidents relational database. Later, we deployed the data source to SQL Server Analysis Services.

Step 2: Create the data source view

We created the data source view which is the link between UK accidents relational database and the analysis services database Team12_MDM.

While creating the New Data Source View we had the option to include Accidents Master fact table. Later, we added the related tables. After the DSV is created within visual studio, it must be deployed to view the DSV within SQL Server Management Studio. This DSV becomes / acts as the relational database.

The above screenshot shows the DSV created within visual studio. It shows all the Dimension tables and Accident_Master Fact table.

We used the DimAccidents (renamed as Accidents) table within the DSV to create the analysis services Accidents Dimension.

Similarly, we used DimVehicles, DimDate, DimCasualties tables within DSV (all renamed as shown in the above screenshot) and created the analysis services Vehicle, Date and Casualties Dimensions.

Named Calculations Creation

Named calculations refer to the new attributes created within the table. We use T-SQL since the DSV tables are relational databases.

- **Month_desc:** is the concatenation of month and year
CASE

```

WHEN month = 1 THEN CONCAT('January',' ',year)
WHEN month = 2 THEN CONCAT('February',' ',year)
WHEN month = 3 THEN CONCAT('March',' ',year)
WHEN month = 4 THEN CONCAT('April',' ',year)
WHEN month = 5 THEN CONCAT('May',' ',year)
WHEN month = 6 THEN CONCAT('June',' ',year)
WHEN month = 7 THEN CONCAT('July',' ',year)
WHEN month = 8 THEN CONCAT('August',' ',year)
WHEN month = 9 THEN CONCAT('September',' ',year)
WHEN month = 10 THEN CONCAT('October',' ',year)
WHEN month = 11 THEN CONCAT('November',' ',year)
WHEN month = 12 THEN CONCAT('December',' ',year)

END

```

Edit Named Calculation

Column_name:

Description:

Expression:

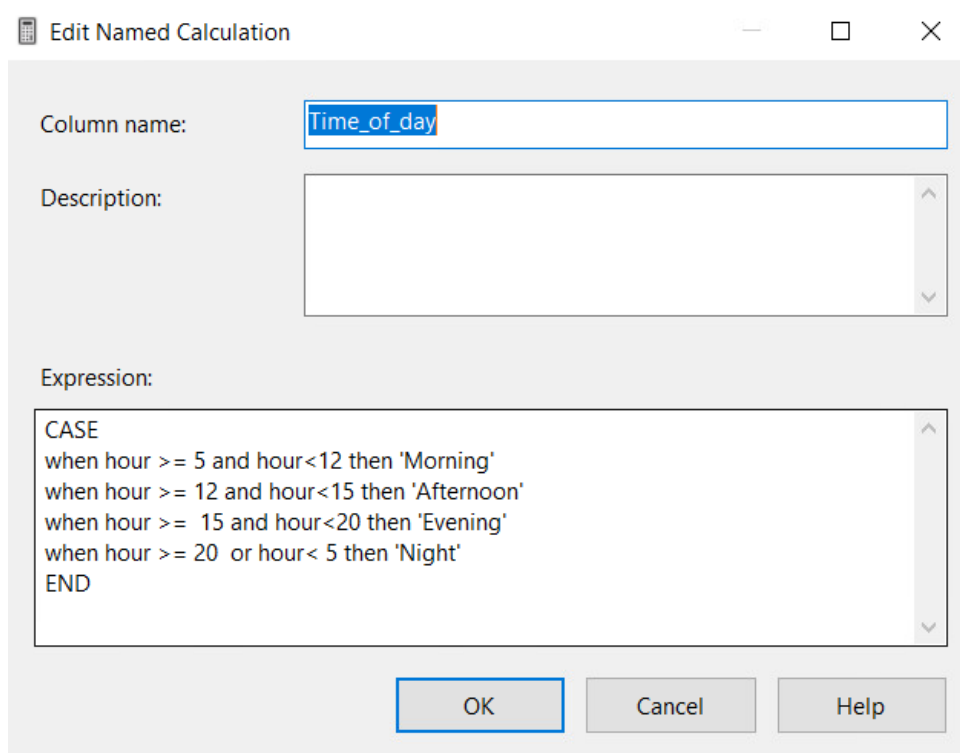

```

CASE
WHEN month = 1 THEN CONCAT('January',' ',year)
WHEN month = 2 THEN CONCAT('February',' ',year)
  WHEN month = 3 THEN CONCAT('March',' ',year)
  WHEN month = 4 THEN CONCAT('April',' ',year)
  WHEN month = 5 THEN CONCAT('May',' ',year)
  WHEN month = 6 THEN CONCAT('June',' ',year)

```

- **Casualty_Class_Desc1:** comprises of casualty class

The screenshot shows a window titled "Edit Named Calculation" with a close button (X) in the top right corner. It contains three main sections: "Column name:", "Description:", and "Expression:". The "Column name:" field contains the text "Casualty_Class_Desc1". The "Description:" field is empty. The "Expression:" field contains a SQL CONCAT statement: `CONCAT ('Casualty_Class', ' ', Casualty_Class)`. At the bottom, there are three buttons: "OK", "Cancel", and "Help".

Column name: Casualty_Class_Desc1

Description:

Expression:

```
CONCAT ('Casualty_Class', ' ', Casualty_Class)
```

OK Cancel Help

- **Casualty_Severity_desc1**: is the concatenation of casualty_class and casualty_severity
i.e. Every casualty class has 3 casualty severities. In the below diagram, we are concatenating casualty class with casualty severity to get a unique record.

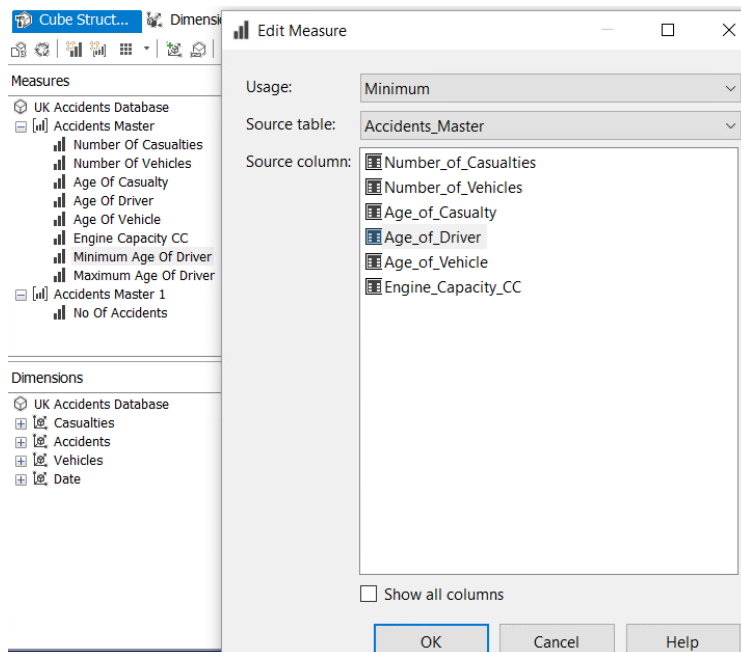

The screenshot shows a dialog box titled "Edit Named Calculation". It has three main sections: "Column name:", "Description:", and "Expression:". The "Column name:" field contains the text "Casualty_Severity_desc1". The "Description:" field is empty. The "Expression:" field contains the SQL expression: `CONCAT('Class',' ',Casualty_Class,'Severity',' ',Casualty_Severity)`. At the bottom of the dialog are three buttons: "OK", "Cancel", and "Help".

- **Casualty_Type_desc1** : is the concatenation of casualty_class, casualty_severity, and casualty_type
i.e. Every casualty class has 3 casualty severities. Every casualty severity has further
types. In the below diagram, we are concatenating casualty class with casualty severity
and casualty type to get a unique record.

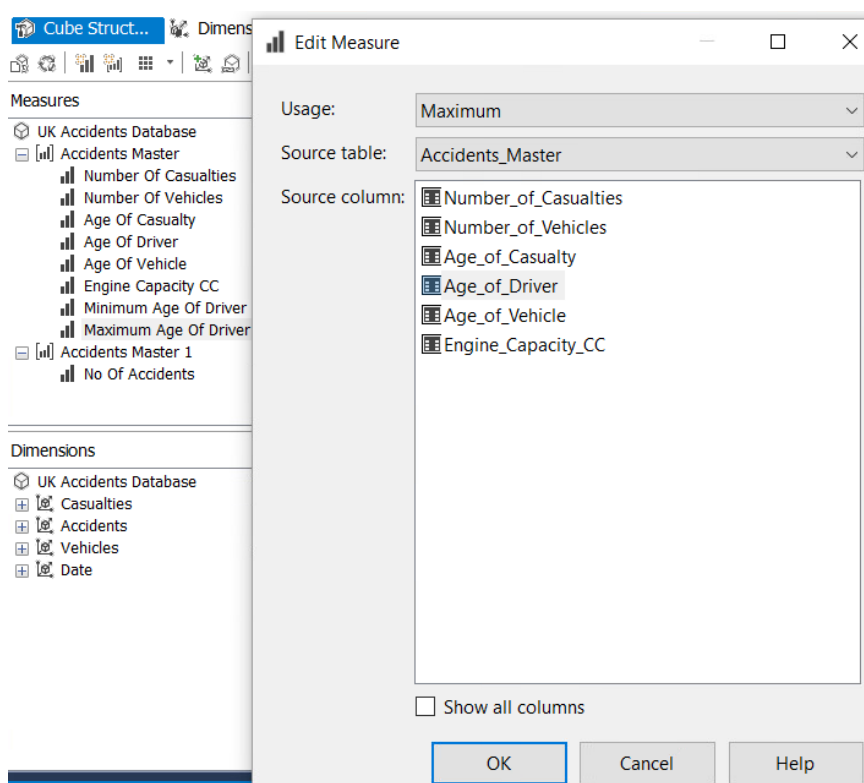

The screenshot shows a dialog box titled "Edit Named Calculation". It has three main sections: "Column name:", "Description:", and "Expression:". The "Column name:" field contains the text "Casualty_Type_desc1". The "Description:" field is empty. The "Expression:" field contains the SQL expression: `CONCAT('Class',' ',Casualty_Class,'Severity',' ',Casualty_Severity,'Type',' ',Casualty_Type)`. At the bottom of the dialog are three buttons: "OK", "Cancel", and "Help".

New Measures

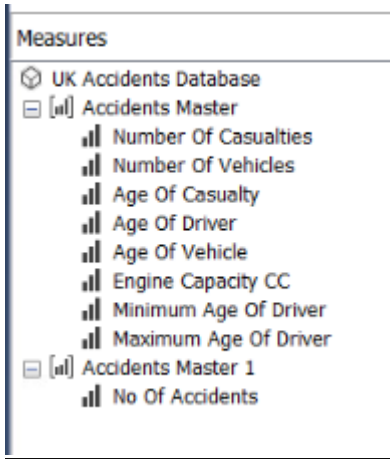

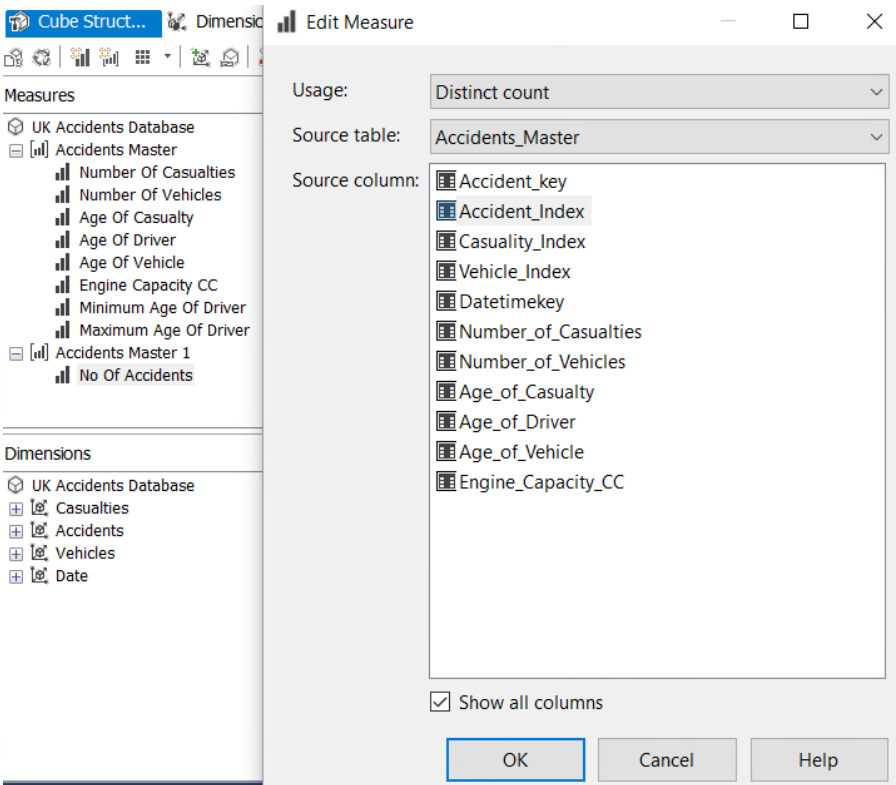

- **Minimum Age Of Driver Measure**

- **Maximum Age Of Driver Measure**

- **No of accidents Measure**

The above screenshot shows all the 3 measures created.

Hierarchy

Hierarchies permit us to drill across, drill-down and roll up aggregates. We need to fix the keycolumn and name column values found within the attributes of the dimension.

Date Hierarchy Key columns and named columns fixing

In-order to have unique values for a month description , we used a composite key which contains month within a given year. For instance, January month is available across all the years in the data source we have. To have a unique record of January, we concatenate Jan with CY and Year. i.e. the month name is not January but January CY 2015 . Similarly we have set composite keycolumns for Quarters and half-year as shown below

UK Accidents Database Cube

We built the UK Accidents Database Cube using Vehicles, Accidents,date and Casualties dimensions.

Partitions and Aggregation

Partitions are used to manage and store data and aggregations for a measure group within a cube. When we process a partition, data is brought into the partition from the source. (Reference: Lecture 6 Part B slide 25)

We have created and deployed 2 partitions of the Accidents Masters Fact table (datetimekey – one up to year 2010, the other after 2010).

The 1st partition includes any dates less than 2010 and the 2nd partition is based on the dates greater than 2010.

⚙ Accidents Master (2 Partitions)

Partition Name	Source	Estimated Rows	Storage Mode	Aggregation Design
1 Accidents Master After 2010	SELECT [dbo].[Accidents_Master].[Accident_key],[dbo].[Accidents_Master...	0	MOLAP	AggregationDesign 30 percent
2 Accidents Master upto 2010	SELECT [dbo].[Accidents_Master].[Accident_key],[dbo].[Accidents_Master...	2779598	MOLAP	AggregationDesign 30 percent

[New Partition...](#)

[Storage Settings...](#)

We created Aggregations in each partition for 30% Performance.

	Aggregations	Estimated Partition Size	Partitions
[-] Accidents Master (1 Aggregation Design)			
[-] AggregationDesign 30 percent	2	2779598	Accidents Master upto 2010, Accidents Master After 2010
[+] Accidents Master 1 (0 Aggregation Designs)			

MDX Queries

10. Display the number of casualties for all years using GENERATE function.

The screenshot shows the SQL Server Enterprise Manager interface. The top pane displays the query text:

```
SELECT [Measures].[Number Of Casualties] ON 0,  
GENERATE([Date].[Year].MEMBERS,  
{[Date].[Year].CURRENTMEMBER} +  
{[Date].[Year].CURRENTMEMBER.FIRSTCHILD}) ON 1  
FROM [UK Accidents Database]
```

The bottom pane shows the query results in a table format:

	Number Of Casualties
All	9875213
2005	1060832
2006	1004696
2007	993009
2008	904923
2009	857946
2010	814998
2011	932853
2012	753827
2013	1016354
2014	773049
2015	762726

The status bar at the bottom indicates: Query executed successfully. | stwssbql01.ad.okstate.edu | OSU\anchitt | Team12_MDM | 00:00:01

Data Mining

Data mining involves exploring and analyzing large data to discover the hidden patterns and rules. It's basically a technique used to predict future outcomes. ([DataMining](#))

The above pictures show the attributes of Accidents and Vehicles tables. We decided to predict accident severity. To decide on the contributing factors for accident severity, it was necessary to learn more about each attribute in both the above tables.

Accident Severity (we will be predicting this)

This is the target variable or the variable we would be predicting. As seen below, the accident severity which is 'Slight' has highest number of records within accidents table.

SQLQuery1.sql - st...(OSU\rkambad (64))*

```
SELECT *
FROM [dbo].[Accident_Severity]
```

100 %

Results Messages

	Accident_Severity	Accident_Severity_Desc
1	1	Fatal
2	2	Serious
3	3	Slight

SQLQuery1.sql - st...(OSU\rkambad (64))*

```
SELECT COUNT(*) , Accident_Severity
FROM [dbo].[DimAccidents]
GROUP BY Accident_Severity
```

100 %

Results Messages

	(No column name)	Accident_Severity
1	22998	1
2	242080	2
3	1515575	3

Road_Type

We understand that road type plays an important role in predicting the severity of an accident. To find out what each road type numerical value within the Accidents table meant, we queried the Road_Type table.

As seen below, we will consider all the road type values except road type = -1 or road type = 9 to predict the accident severity.

SQLQuery4.sql - st...(OSU\rkambad (55))* DMXQuery1.dmx -...DM

```
SELECT *
FROM [dbo].[Road_Type]
```

100 %

Results Messages

	Road_Type	Road_Type_Desc
1	-1	Data missing or out of range
2	1	Roundabout
3	2	One way street
4	3	Dual carriageway
5	6	Single carriageway
6	7	Slip road
7	9	Unknown
8	12	One way street/Slip road

Light condition

Light condition is another factor which greatly influences driving. Darkness while driving leads to accidents. To find out what each numerical value of light_conditions within the Accidents table meant, we queried the Light_conditions table.

As seen below, we will consider all the road type values except road type = -1 to predict the accident severity

The screenshot shows a SQL query window with the following query:

```
SELECT *
FROM [dbo].[Light_Conditions]
```

The results pane displays the following data:

	Light_Conditions	Light_Conditions_Desc
1	-1	Data missing or out of range
2	1	Daylight
3	4	Darkness - lights lit
4	5	Darkness - lights unlit
5	6	Darkness - no lighting
6	7	Darkness - lighting unknown

Weather Conditions

Weather also helps in predicting accidents. Although we didn't have any table that specifically explains what each numerical value of weather conditions within the Accidents table meant, we decided to consider all numerical values except weather_condition = -1 (believing it to be unknown or missing values) to predict accident severity.

The screenshot shows a SQL query window with the following query:

```
SELECT DISTINCT [Weather_Conditions]
FROM [dbo].[DimAccidents]
```

The results pane displays the following data:

	Weather_Conditions
1	-1
2	1
3	2
4	3
5	4
6	5
7	6
8	7
9	8
10	9

Road Surface Condition

The condition of roads may also help in predicting accident severity. We decided to consider all the values except road_surface_conditions = -1 for predicting accident severity.

SQLQuery4.sql - st...(OSU\rkambad (55))* - X DMXQuery1.dmx -...

```
SELECT DISTINCT Road_Surface_Conditions
FROM [dbo].[DimAccidents]
```

100 %

Results Messages

	Road_Surface_Conditions
1	-1
2	1
3	2
4	3
5	4
6	5

Special Conditions at Site

We decided to eliminate special conditions at site = -1 while predicting accident severity. Although we do not know what special_conditions_at_site = 0 meant, based on the large number of records available, we decided to consider this value also for predicting accident severity.

SQLQuery4.sql - st...(OSU\rkambad (55))* - X DMXQuery1.dmx

```
SELECT COUNT(*) ,
       Special_Conditions_at_Site
FROM [dbo].[DimAccidents]
GROUP BY Special_Conditions_at_Site
```

100 %

Results Messages

	(No column name)	Special_Conditions_at_Site
1	124	-1
2	1736828	0
3	3263	1
4	901	2
5	2616	3
6	20741	4
7	4293	5
8	6222	6
9	5665	7

Urban Rural

We know that accidents happen more in urban areas compared to rural as the number of vehicles operating in urban areas are more. We think that the value of 1 indicates urban and a 2 indicates rural. Although there are only 143 records for urban_rural =3 within the accidents table, we decided to use all the three values of urban_rural to predict accident severity.

SQLQuery4.sql - st...(OSU\rkambad (55))* DMXQ

```
SELECT COUNT(*) ,
       Urban_Rural
FROM [dbo].[DimAccidents]
GROUP BY Urban_Rural
```

100 %

Results Messages

	(No column name)	Urban_Rural
1	1146421	1
2	634089	2
3	143	3

Junction detail

A junction is where two or more roads meet. It may also influence the accident severity. Hence, we are using this variable within our mining structure. We will not consider junction_detail = -1 for predicting accident severity.

SQLQuery4.sql - st...(OSU\rkambad (55))* DMXQuer

```
SELECT COUNT(*) ,
       [Junction_Detail]
FROM [dbo].[DimAccidents]
GROUP BY [Junction_Detail]
```

100 %

Results Messages

	(No column name)	Junction_Detail

2	716544	0
3	154723	1
4	19206	2
5	553692	3
6	26054	5
7	170738	6
8	23060	7
9	65219	8
10	51398	9

Junction Control

We will not consider junction_control=-1 for predicting the accident severity.

SQLQuery4.sql - st...(OSU\rkambad (55))* DMXQuery1.dm

```
SELECT COUNT(*)
      Junction_Control
FROM [dbo].[DimAccidents]
GROUP BY Junction_Control
```

100 %

Results Messages

	(No column name)	Junction_Control
1	641392	-1
2	76916	0
3	2918	1
4	182829	2
5	10841	3
6	865757	4

Vehicle Type

The type of vehicle whether car, cycle and a motorcycle etc may also help in predicting accident severity.

SQLQuery4.sql - st...(OSU\rkambad (55))* DMXQuery1.dm

```
SELECT *
FROM [dbo].[Vehicle_Type]
```

100 %

Results Messages

	Vehicle_Type	Vehicle_Type_Desc
1	-1	Data missing or out of range
2	1	Pedal cycle
3	2	Motorcycle 50cc and under
4	3	Motorcycle 125cc and under
5	4	Motorcycle over 125cc and up to 500cc
6	5	Motorcycle over 500cc
7	8	Taxi/Private hire car
8	9	Car
9	10	Minibus (8 - 16 passenger seats)
10	11	Bus or coach (17 or more pass seats)
11	16	Ridden horse
12	17	Agricultural vehicle
13	18	Tram
14	19	Van / Goods 3.5 tonnes mgw or under
15	20	Goods over 3.5t. and under 7.5t
16	21	Goods 7.5 tonnes mgw and over
17	22	Mobility scooter
18	23	Electric motorcycle

19	90	Other vehicle
20	97	Motorcycle - unknown cc
21	98	Goods vehicle - unknown weight

Vehicle Manoeuvre

To understand what each numerical value of vehicle_manoeuvre meant within the accidents table, we queried the Vehicle Manoeuvre table. The description of the values can be seen in the below screenshot. Whether a vehicle was taking a U-turn, overtaking another or changing lanes may also help in predicting accident severity.

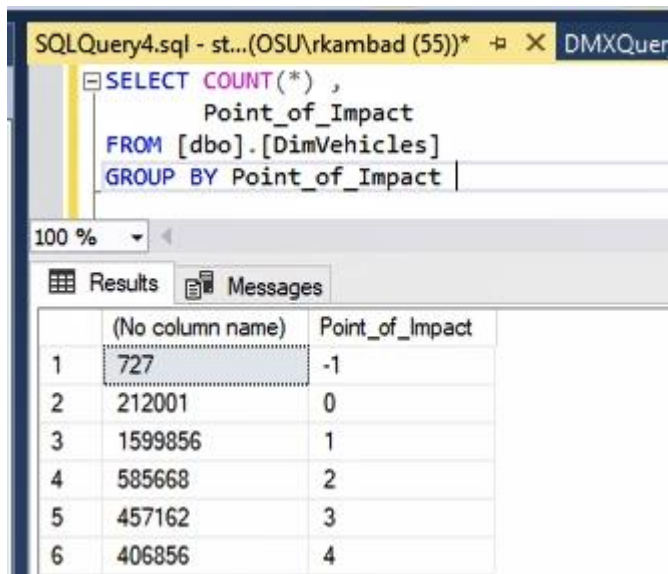

We won't consider vehicle_manoeuvre = -1 for our mining models.

	Vehicle_Manoeuvre	Vehicle_Manoeuvre_Desc
1	-1	Data missing or out of range
2	1	Reversing
3	2	Parked
4	3	Waiting to go - held up
5	4	Slowing or stopping
6	5	Moving off
7	6	U-turn
8	7	Turning left
9	8	Waiting to turn left
10	9	Turning right
11	10	Waiting to turn right
12	11	Changing lane to left
13	12	Changing lane to right
14	13	Overtaking moving vehicle - offside
15	14	Overtaking static vehicle - offside
16	15	Overtaking - nearside
17	16	Going ahead left-hand bend
18	17	Going ahead right-hand bend

Point of Impact

We think that the point of impact refers to whether the impact was on the left, right, front or rear of the vehicle etc. We will consider all the values for point of impact except -1

The screenshot shows a SQL query window with the following text:

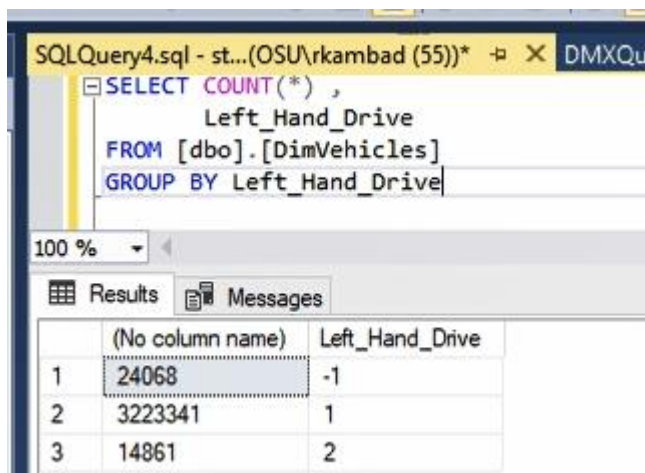

```
SQLQuery4.sql - st...(OSU\rkambad (55))* DMXQuer
SELECT COUNT(*) ,
       Point_of_Impact
FROM [dbo].[DimVehicles]
GROUP BY Point_of_Impact
```

Below the query, the 'Results' tab is active, displaying a table with two columns: '(No column name)' and 'Point_of_Impact'. The table contains six rows of data.

	(No column name)	Point_of_Impact
1	727	-1
2	212001	0
3	1599856	1
4	585668	2
5	457162	3
6	406856	4

Left Hand Drive

We will not consider the left_hand_drive = -1 for our mining models.

The screenshot shows a SQL query window with the following text:

```
SQLQuery4.sql - st...(OSU\rkambad (55))* DMXQuer
SELECT COUNT(*) ,
       Left_Hand_Drive
FROM [dbo].[DimVehicles]
GROUP BY Left_Hand_Drive
```

Below the query, the 'Results' tab is active, displaying a table with two columns: '(No column name)' and 'Left_Hand_Drive'. The table contains three rows of data.

	(No column name)	Left_Hand_Drive
1	24068	-1
2	3223341	1
3	14861	2

Sex of Driver

The sex of the driver may also help in predicting accident severity. We have considered only the values sex of driver = 1 or 2 to predict the severity of accidents.

	(No column name)	Sex_of_Driver
1	52	-1
2	2147401	1
3	924565	2
4	190252	3

	Sex_of_Driver	Sex_of_Driver_Desc
1	-1	Data missing or out of range
2	1	Male
3	2	Female
4	3	Not known

Journey Purpose

Journey purpose may also help in predicting the severity of an accident. We will not consider journey_purpose = -1 for our mining model.

	(No column name)	Journey_Purpose
1	44945	-1
2	545046	1
3	1362699	15
4	311840	2
5	31786	3
6	11118	4
7	22462	5
8	932374	6

Based on the above analysis of the attributes within Accidents and Vehicle table, we used the following attributes to predict accident severity.

Attributes from accidents table

- Accident_Index - Key column which uniquely identifies an entity
- Road_Type
- Speed_limit
- Light_Conditions
- Weather_Conditions
- Road_Surface_Conditions
- Special_Conditions_at_Site
- Urban_Rural
- Junction_Detail
- Junction_Control

Attributes from Vehicles table

- Vehicle_Type
- Vehicle_Manoeuvre
- Point_of_Impact
- Left_Hand_Drive
- Sex_of_Driver
- Journey Purpose

Various mining models could be built using the above UK Accidents Database. We decided to use the following data mining techniques based on Microsoft data mining algorithms.

- Decision Tree
- Logistic Regression
- Neural Networks

Creating the Mining Structure

We will use the CREATE MINING STRUCTURE DMX statement to create the mining structure. Since we will be creating many mining models, we will use ALTER MINING STRUCTURE statement to add mining models to the structure.

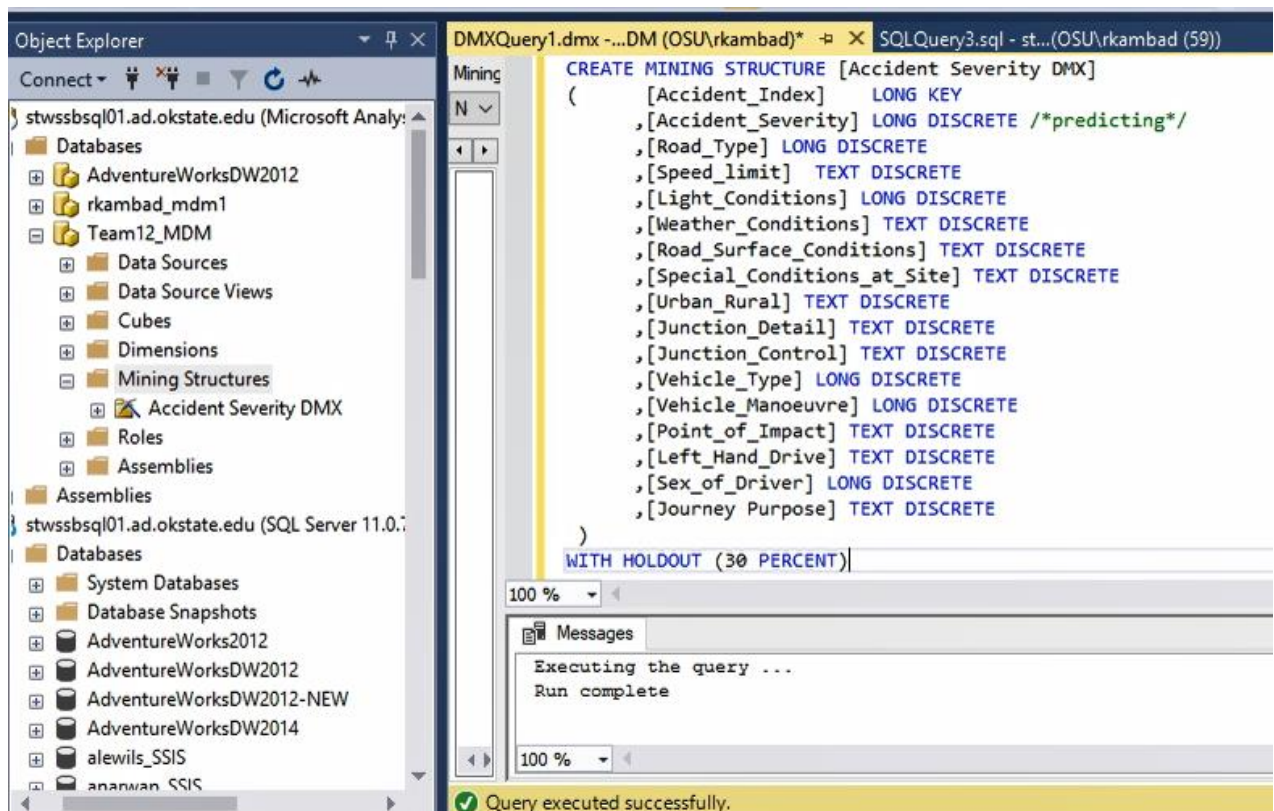

The name of the mining structure we created is : Accident Severity DMX

```
CREATE MINING STRUCTURE [Accident Severity DMX]
(
  [Accident_Index] LONG KEY
  ,[Accident_Severity] LONG DISCRETE /*predicting*/
  ,[Road_Type] LONG DISCRETE
  ,[Speed_limit] TEXT DISCRETE
  ,[Light_Conditions] LONG DISCRETE
  ,[Weather_Conditions] TEXT DISCRETE
  ,[Road_Surface_Conditions] TEXT DISCRETE
  ,[Special_Conditions_at_Site] TEXT DISCRETE
  ,[Urban_Rural] TEXT DISCRETE
  ,[Junction_Detail] TEXT DISCRETE
  ,[Junction_Control] TEXT DISCRETE
  ,[Vehicle_Type] LONG DISCRETE
  ,[Vehicle_Manoeuvre] LONG DISCRETE
  ,[Point_of_Impact] TEXT DISCRETE
  ,[Left_Hand_Drive] TEXT DISCRETE
  ,[Sex_of_Driver] LONG DISCRETE
  ,[Journey Purpose] TEXT DISCRETE
)
WITH HOLDOUT (30 PERCENT)
```

The key column for the mining structure uniquely identifies an entity in the source data. We have also defined the mining columns. Additionally, we specified what portion of the data is used for testing mining models. The remaining data is used for training the models.

By default, analysis services will create a test data set which contains 30% of all the data. We can also add a specification that the test data set should contain 30% of the cases up to a maximum of 1000 cases. (reference lecture 7, slide no. 17)

In the below screenshot, we see the Accident Severity DMX mining structure created under the Mining Structure folder.

Creating Mining Models

After identifying the mining structure, we will use the ALTER MINING STRUCTURE STATEMENT to alter the mining structure and add mining models.

It is necessary to define the predictable and the input columns. Additionally, we must determine which algorithm to use.

As stated earlier, we will use the following data mining techniques based on Microsoft data mining algorithms.

- Decision Tree
- Logistic Regression
- Neural Networks

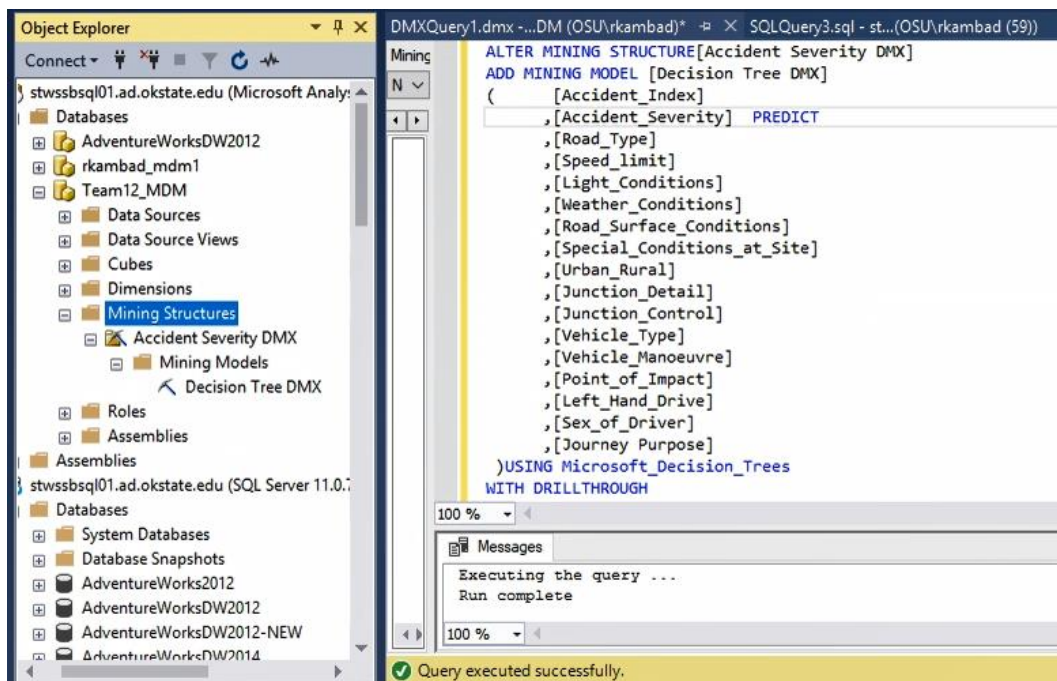

Model1: Decision Tree Mining Model

ALTER MINING STRUCTURE[Accident Severity DMX]

ADD MINING MODEL [Decision Tree DMX]

```
(
  [Accident_Index]
  ,[Accident_Severity] PREDICT
  ,[Road_Type]
  ,[Speed_limit]
  ,[Light_Conditions]
  ,[Weather_Conditions]
  ,[Road_Surface_Conditions]
  ,[Special_Conditions_at_Site]
  ,[Urban_Rural]
  ,[Junction_Detail]
  ,[Junction_Control]
  ,[Vehicle_Type]
  ,[Vehicle_Manoeuvre]
  ,[Point_of_Impact]
  ,[Left_Hand_Drive]
  ,[Sex_of_Driver]
  ,[Journey Purpose]
) USING Microsoft_Decision_Trees
WITH DRILLTHROUGH
```

In the below screenshot, we see the Decision Tree DMX mining model created under Accident Severity DMX mining structure.

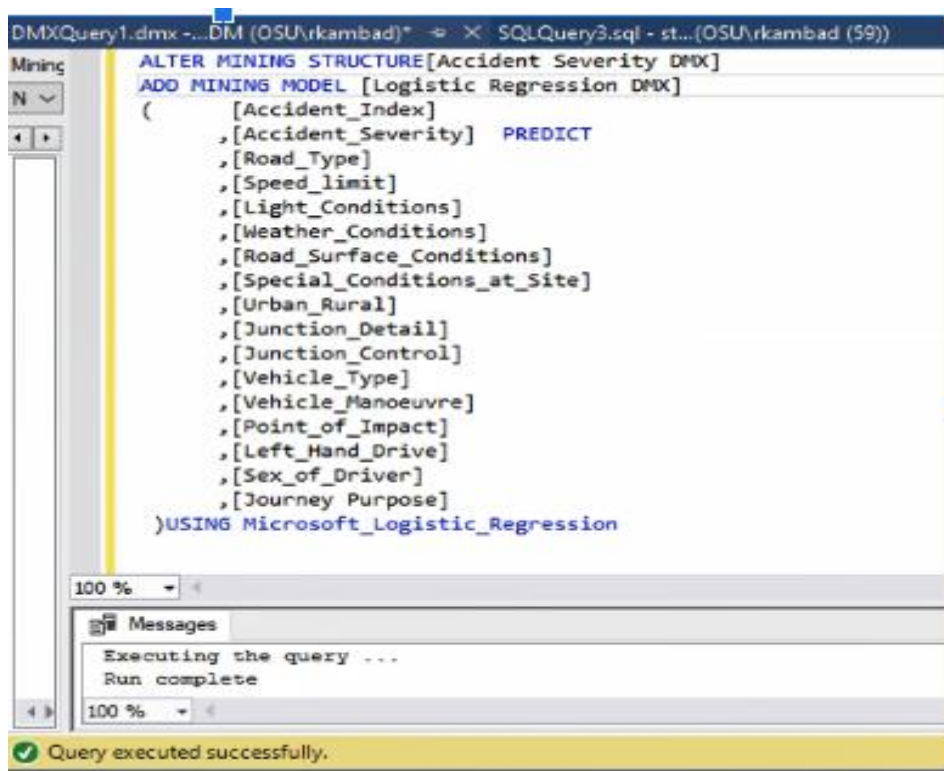

Model2: Logistic Regression Mining Model

ALTER MINING STRUCTURE[Accident Severity DMX]

ADD MINING MODEL [Logistic Regression DMX]

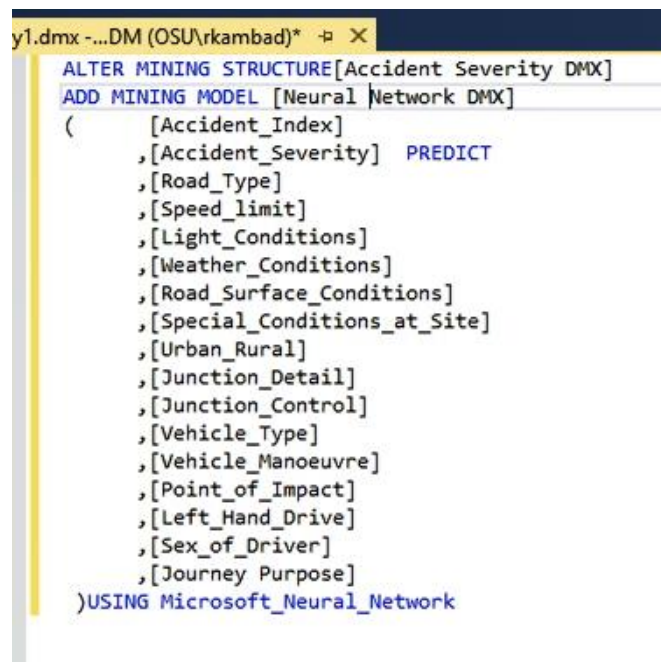

```
(  [Accident_Index]
  ,[Accident_Severity] PREDICT
  ,[Road_Type]
  ,[Speed_limit]
  ,[Light_Conditions]
  ,[Weather_Conditions]
  ,[Road_Surface_Conditions]
  ,[Special_Conditions_at_Site]
  ,[Urban_Rural]
  ,[Junction_Detail]
  ,[Junction_Control]
  ,[Vehicle_Type]
  ,[Vehicle_Manoeuvre]
  ,[Point_of_Impact]
  ,[Left_Hand_Drive]
  ,[Sex_of_Driver]
  ,[Journey Purpose]
)USING Microsoft_Logistic_Regression
```

In the below screenshot, we see the Logistic Regression DMX mining model created under Accident Severity DMX mining structure.

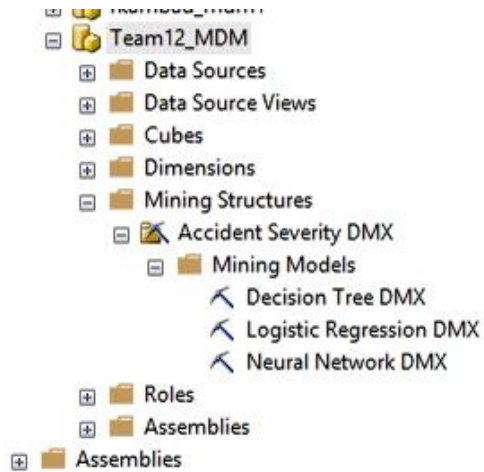

Model3: Neural Networks Mining Model

```
ALTER MINING STRUCTURE[Accident Severity DMX]
ADD MINING MODEL [Neural Network DMX]
( [Accident_Index]
  ,[Accident_Severity] PREDICT
  ,[Road_Type]
  ,[Speed_limit]
  ,[Light_Conditions]
  ,[Weather_Conditions]
  ,[Road_Surface_Conditions]
  ,[Special_Conditions_at_Site]
  ,[Urban_Rural]
  ,[Junction_Detail]
  ,[Junction_Control]
  ,[Vehicle_Type]
  ,[Vehicle_Manoeuvre]
  ,[Point_of_Impact]
  ,[Left_Hand_Drive]
  ,[Sex_of_Driver]
  ,[Journey Purpose]
)USING Microsoft_Neural_Network
```

A screenshot of a SQL query editor window. The title bar shows the file path 'y1.dmx - ...DM (OSU\rkambad)*' and standard window controls. The editor contains the same SQL code as the previous block, with syntax highlighting: 'ALTER MINING STRUCTURE' and 'ADD MINING MODEL' are in blue, 'PREDICT' is in blue, and the rest of the code is in black. A yellow vertical line is visible on the left side of the editor, likely a scrollbar or a selection indicator.

The below screenshot shows all the three mining models we created under the Accident Severity mining structure.

```
INSERT INTO MINING STRUCTURE [Accident Severity DMX]

Model 1: Decision Tree

1st Level

From the above decision tree output, we see that whether the point of impact is front, rear, left or right, it is the most important factor in predicting accident severity.

2nd Level

Depending upon the point of impact,

- If the point of impact is 3, the accident severity depends on location if it is urban or rural.
- If the point of impact is 2, the accident severity depends on the vehicle manoeuvre or not.
- If the point of impact is 1, the accident severity depends on the vehicle type.

Mining Legend

High

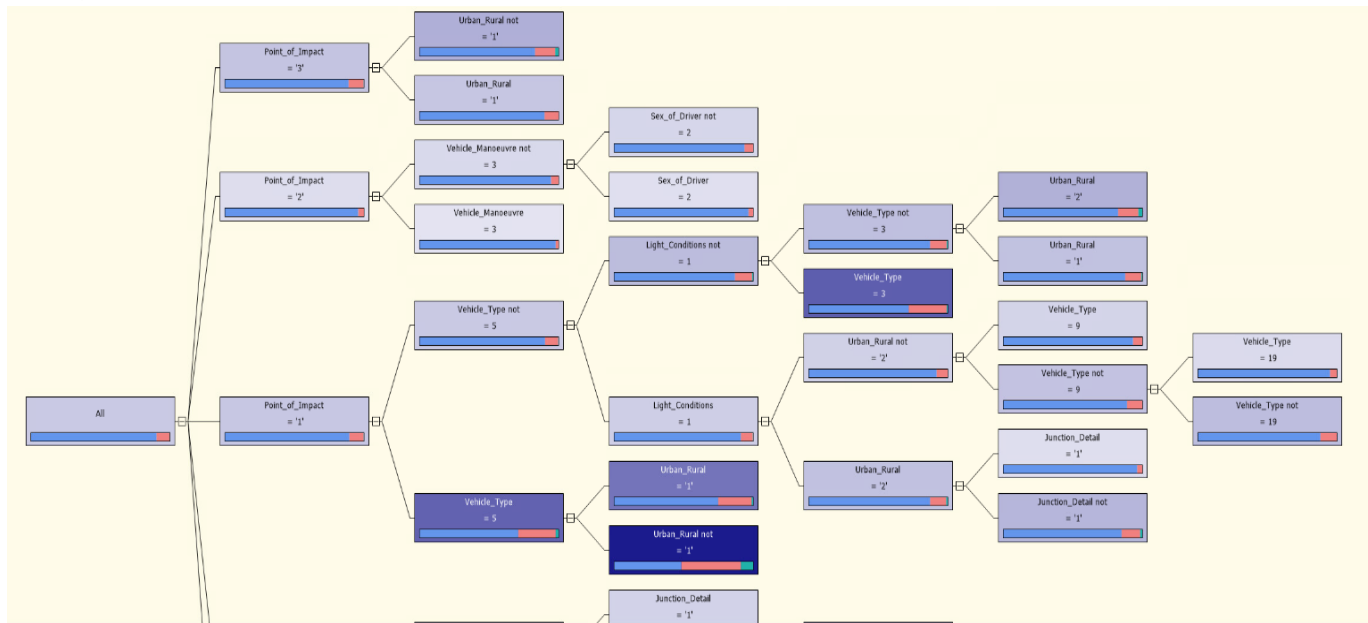

Low

Total Cases: 5186

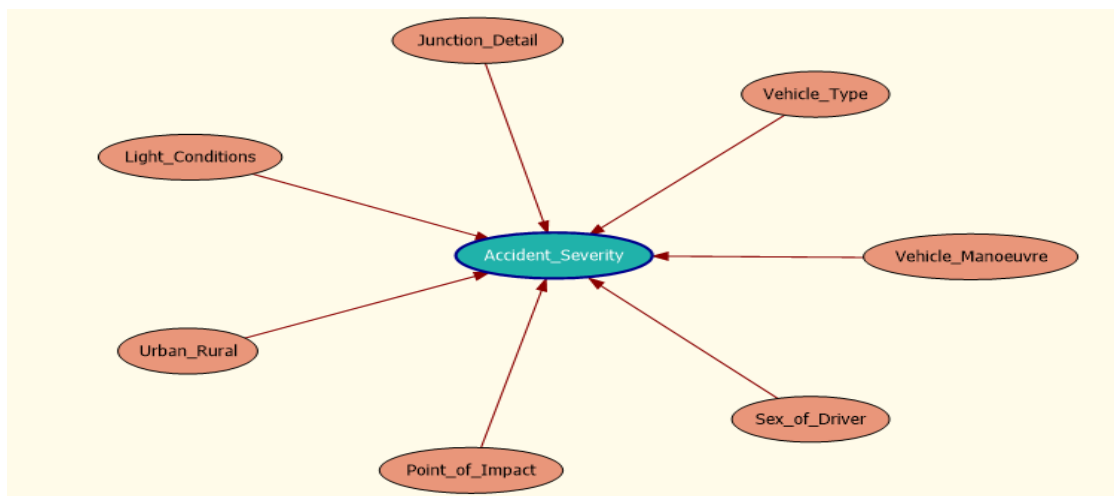

Value	Cases	Probability	Histogram
<input checked="" type="checkbox"/> 1	95	1.85%	
<input checked="" type="checkbox"/> 2	686	13.24%	
<input checked="" type="checkbox"/> 3	4405	84.91%	

Point_of_Impact = '0'

Complete Decision Tree

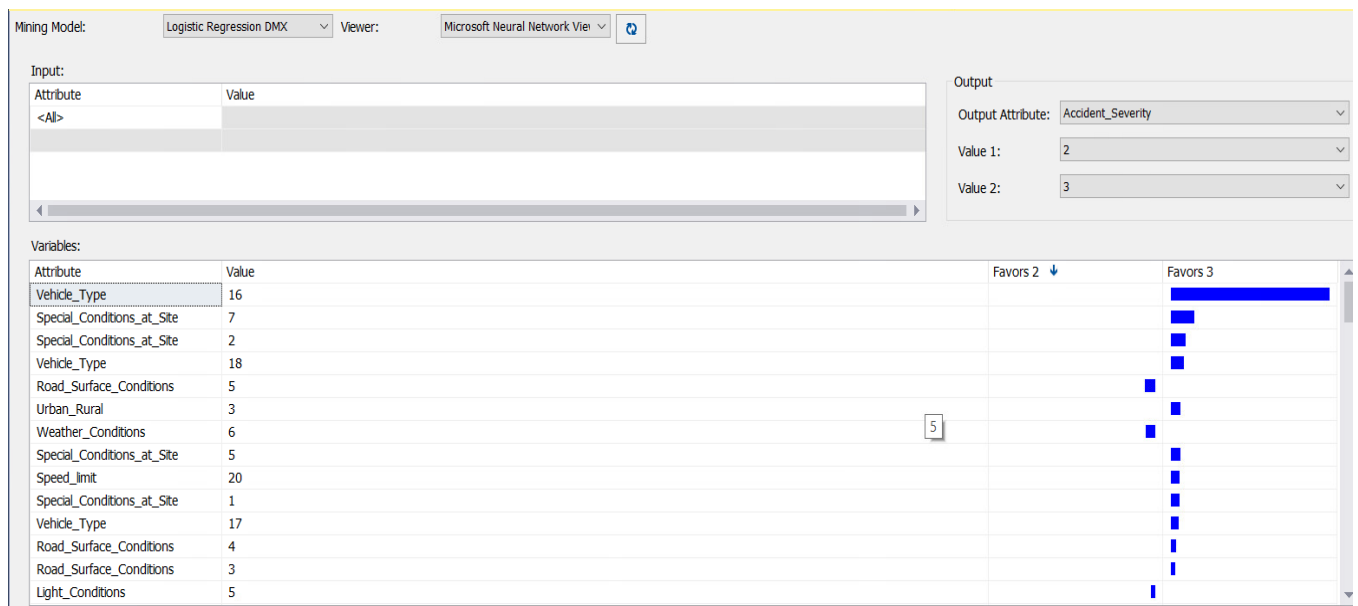

Dependency Network

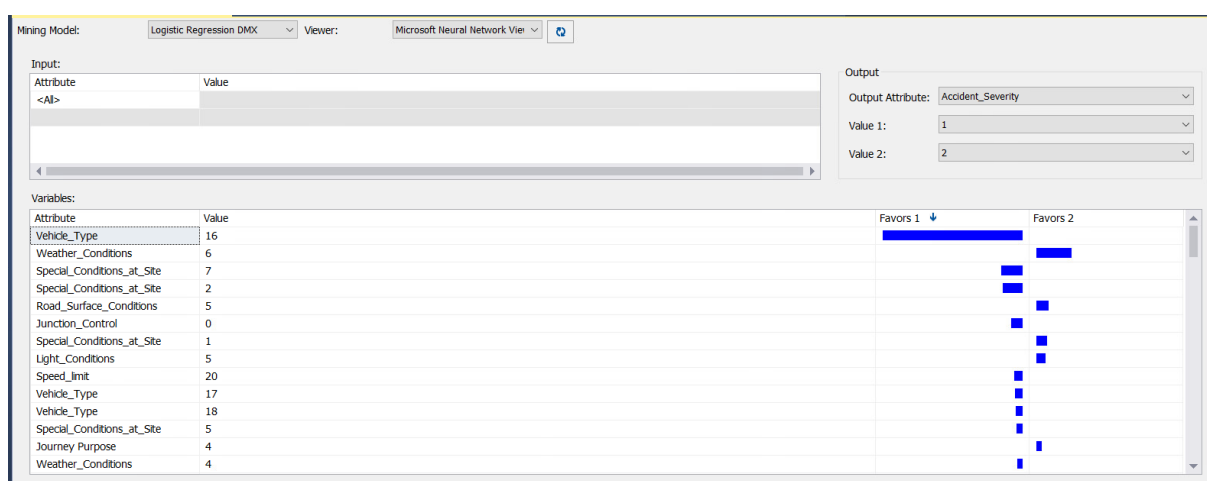

From the above screenshots of the complete decision tree and dependency network, we conclude that point of impact, location whether urban_rural, light conditions, junction detail, vehicle type, vehicle manoeuvre, sex of the driver play good roles in predicting accident severity.

Model 2: Logistic Regression

From the above logistic regression output we can say that, when we are considering Accident Severity 2 and 3, Vehicle_Type value =16 favours Accident Severity= 3. Special_conditions_at_site=7 is the next important variable which favours Accident Severity 3 the most.

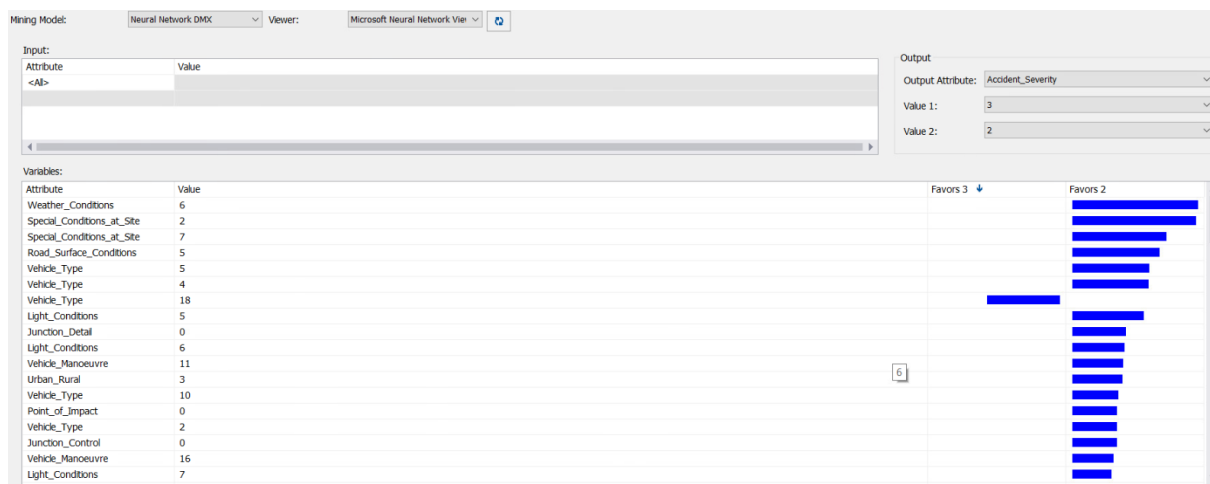

In similar manner when we are considering Accident Severity 1 and 2, vehicle_Type value 16 favours Accident Severity 1 and Weather_Conditions = 6 favours Accident Severity 2 the most.

Model3: Neural Network

The Microsoft Neural Network algorithm combines each possible state of the input attribute with each possible state of the predictable attribute and uses the training data to calculate probabilities.

From the below neural network output we can say that weather condition = 6 favors the Accident_Severity= 2 the most. Also, 2nd most important value is special conditions at site = 2, it favors accident severity 2.

Comparison of the results

Lift Chart

Lift chart helps us to visualize the improvement we get when we use a data mining model when compared to the random guess model. Using the mining structure test cases, we constructed the lift chart for all the 3 mining models for accident severity = 1 (Fatal)

SQLQuery1.sql - st... (OSU\rkambad (64))*

Decision Tree DMX [Lift Chart] - [X]

Input Selection | Lift Chart | Classification Matrix | Cross Validation

Select predictable mining model columns to show in the lift chart:

☒ Synchronize Prediction Columns and Values

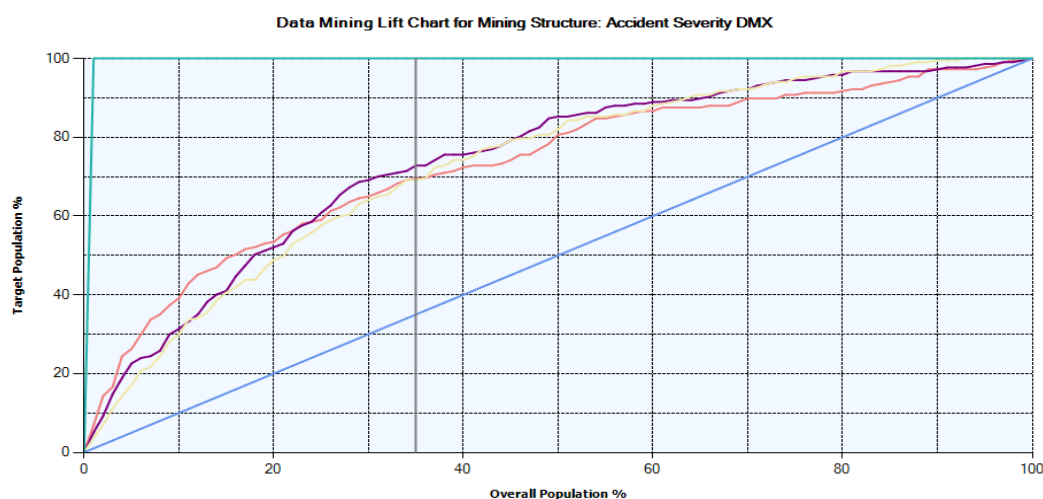

Show	Mining Model	Predictable Column Name	Predict Value
<input checked="" type="checkbox"/>	Decision Tree DMX	Accident_Severity	1
<input checked="" type="checkbox"/>	Logistic Regression DMX	Accident_Severity	1
<input checked="" type="checkbox"/>	Neural Network DMX	Accident_Severity	1

Select data set to be used for Accuracy Chart:

☐ Use mining model test cases

☒ Use mining structure test cases

☐ Specify a different data set

The y-axis is the accuracy measure for the corresponding population percentage we targeted which is 35% (vertical grey line in the above screenshot).

Mining Legend			
Population percentage: 35.00%			
Series, Model	Score	Target population	Predict probability
Decision Tree DMX	0.74	69.59%	0.40%
Logistic Regressio...	0.75	72.81%	2.41%
Neural Network D...	0.73	69.12%	1.17%
Random Guess M...		35.00%	
Ideal Model for: D...		100.00%	

From the above charts, we can say that if we target 35% of the population,

- The Random Guess Model will correctly identify 35% of all the accident severity =1(fatal) within the population
- The ideal line/model for decision tree will correctly identify 100% of all the accident severity =1(fatal) within the population. (slope=1)
- The Decision Tree model will correctly identify 69.6% of all the accident severity =1(fatal) within the population
- The Logistic Regression model will correctly identify 72.81% of all the accident severity =1(fatal) within the population
- The Neural Network model will correctly identify 69.12% of all the accident severity =1(fatal) within the population

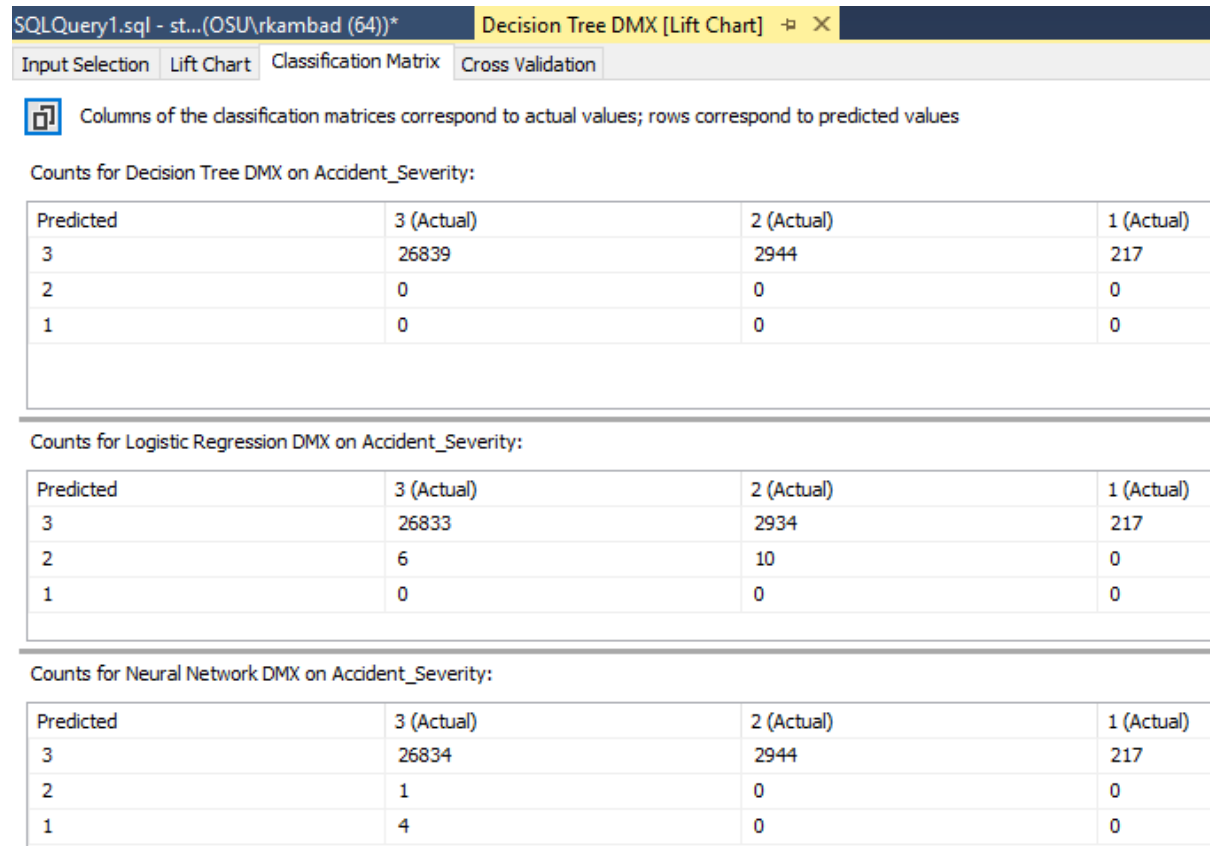

The lift score is highest for Logistic Regression model. (Although, there is not much difference between all the 3 models).

Interpreting Predict probability

- To identify the accidents from the Logistic Regression model which have accident severity = 1(fatal), we need to use a query to retrieve cases with a predict probability of at least 2.41%
- To identify the accidents from Decision Tree model which have accident severity = 1(fatal), we need to use a query to retrieve cases with a predict probability of at least 0.40%
- To identify the accidents from Neural Network model which have accident severity = 1(fatal), we need to use a query to retrieve cases with a predict probability of at least 1.71%

(Reference for lift score, chart, predict probability: Lecture 7 slide 39)

Classification Matrix

Classification interpretations

Decision tree model results predicted that 26,839 accidents would have had accident severity level 3 correctly. 2,944 accidents who has severity level 3, predicted wrongly that it has severity level 2. And 217 accidents who has severity level 3, predicted wrongly that it has severity level 1.

Logistic regression model results predicted that 26,833 accidents would have had accident severity level 3 correctly. 2,934 accidents who has severity level 3, predicted wrongly that it has severity level 2. And 217 accidents who has severity level 3, predicted wrongly that it has severity level 1.

Neural network model results predicted that 26,834 accidents would have had accident severity level 3 correctly. 2,944 accidents who has severity level 3, predicted wrongly that it has severity level 2. And 217 accidents who has severity level 3, predicted wrongly that it has severity level 1.

Cross Validation

We have specified target state = 1 (accident severity = 1 or fatal) and a target threshold = 0.2

Fold Count:	<input type="text" value="5"/>	Max Cases:	<input type="text" value="0"/>	<input type="button" value="Get Results"/>	
Target Attribute:	<input type="text" value="Accident_Severity"/>	Target State:	<input type="text" value="1"/>	Target Threshold:	<input type="text" value="0.2"/>

3	Neural Networks Model	0.006	-0.3551	0.135

Summary of the results

Based on our above analysis of all the models, we conclude that decision tree is the best model. Here are the reasons to conclude so.

Lift Chart for accident severity =1

Mining Legend

Population percentage: 35.00%

Series, Model	Score	Target population	Predict probability
Decision Tree DMX	0.74	69.59%	0.40%
Logistic Regression...	0.75	72.81%	2.41%
Neural Network D...	0.73	69.12%	1.17%
Random Guess M...		35.00%	
Ideal Model for: D...		100.00%	

Based on the above screenshot after lift chart generation, we see that though the lift score for the logistic regression is good, there is not much great difference in the lift score for decision tree model.

Classification matrix

Counts for Decision Tree DMX on Accident_Severity:

Predicted	3 (Actual)	2 (Actual)	1 (Actual)
3	26839	2944	217
2	0	0	0
1	0	0	0

Decision tree model results predicted that 26,839 accidents would have had accident severity level 3 correctly. 2,944 accidents who has severity level 3, predicted wrongly that it has severity level 2. And 217 accidents who has severity level 3, predicted wrongly that it

has severity level 1.

The prediction of decision model is slightly better than the other two models.

Cross validation

We have specified target state = 1 (accident severity = 1 or fatal) and a target threshold = 0.2

Sl.No.	Model Name	Lift Score	Log Score	RMSE
1	Decision Tree Model	0.0126	-0.348	0.116

- The log score for the decision tree model is also closest to 0. The average prediction probability for the same model is $e^{(-.348)} = 0.7$
- The lift score indicates that there is a 1.26% improvement in the probability of the target outcome when decision tree model is used.

Since the log and lift score for decision tree is slightly good compared to the other two models, decision tree model seems to be a good model built

Conclusion

1. The decision tree model is not only more accurate than other models, but the factors explained by it are also makes sense in real world.
2. Based on whether the point of impact is front of the vehicle, rear, sides etc., we can say how severe an accident is. Also, there will be ideally a greater number of accidents in urban_rural = 1 or 2.
3. The kind of vehicle we travel whether motorcycle 125 cc and under, light conditions and sex of the driver plays important roles in deciding accident severity.
4. Compared to the vehicle which is waiting to go (held up), the vehicles which are turning left or right or changing the lanes, they are prone to accidents.
